

# TransFi MERN Full Stack Developer - What to Learn

## MUST Learn (Class A keywords with no direct project experience)

- **Angular (2+, i.e. modern Angular) & AngularJS (1.x)** – two very different frameworks despite the shared name. Modern Angular is a full TypeScript-first framework with its own component/module/dependency injection system – since you already write TypeScript, the syntax is learnable fast, but its component lifecycle and RxJS-based reactivity are a different mental model from React Hooks. AngularJS (1.x) is the legacy version (\$scope, controllers, two-way binding) – lower priority since it's maintenance-mode. Build one small CRUD app in modern Angular (Angular CLI + a component + a service) to get the core patterns down; skim AngularJS docs just enough to recognize its syntax.
- **Web3.js** – a JavaScript library for talking to Ethereum-compatible blockchains (reading balances, sending transactions, interacting with smart contracts). TransFi's product (crypto on/off-ramping) likely uses this for wallet/transaction integration. Bridge from your existing API-integration experience (Vapi, Stripe webhooks) – Web3.js calls follow a similar "call an API, get a response, handle async" pattern, just against a blockchain node (via Infura/Alchemy) instead of a REST endpoint. Build one small script that connects to a testnet and reads a wallet balance.
- **Blockchain fundamentals** – the concepts underneath Web3.js: wallets, transactions, gas fees, smart contracts, and the difference between on-chain and off-chain data. You don't need to write Solidity for this role, but understanding what a transaction hash and a smart contract call actually do will matter in a crypto on/off-ramp context (TransFi's core product).

## GOOD to Learn (strengthens the application, not blocking)

- **Server-Oriented Architecture (SOA) terminology** – you already build RESTful APIs and microservices-adjacent systems (Echo's multi-tenant architecture, Vibe's tRPC backend); the gap here is mostly vocabulary – being able to name concepts like service contracts and loose coupling that you already practice.
- **Crypto on/off-ramping domain knowledge** – skim how a crypto exchange/on-ramp actually works (KYC, fiat-to-crypto conversion, compliance checks) so you can speak to TransFi's specific product during interviews, even though this is domain knowledge rather than a coding skill.

## Fast-Ramp Note

Your core stack IS the M-E-N in MERN (MongoDB, Express.js, Node.js) plus React – this is your strongest-matching JD to date. Angular is the one new framework paradigm to learn, and Web3.js/blockchain is the one new domain. Prioritize a small Angular CRUD app first since it's the larger keyword ask (both versions listed), then a minimal Web3.js wallet-read script to speak credibly about blockchain integration in an interview.
