

Dentsu (Sokrati) Developer - What to Learn

Why these keywords

This is an entry-level full-stack JD leaning on Python (Flask/Django) for the backend, alongside React.js on the frontend, MySQL/MongoDB, and Postman for API testing. Your React and REST API experience map directly; the delta is mostly the Python web-framework layer and formal API-testing tooling.

MUST learn (Class A – explicitly required)

Flask / Django – Python web frameworks for building REST APIs, the same role Express.js plays in your Node.js work. Bridge: Flask is closer to Express (minimal, unopinionated, you wire up routes yourself); Django is more like a "batteries-included" framework (built-in ORM, admin panel, auth) similar in spirit to how Next.js bundles routing + rendering. 20% to know: Flask – create a route with '@app.route', return JSON, understand a basic app factory pattern. Django – understand models/views/urls.py structure and the Django ORM (comparable to Prisma/Mongoose query syntax you already know).

MySQL – you already know SQL (Skimly, PostgreSQL) – MySQL syntax is nearly identical to Postgres for basic queries; note differences like 'AUTO_INCREMENT' vs 'SERIAL' and slightly different date functions. 20%: run basic CRUD + JOIN queries in MySQL Workbench or a CLI client.

Postman – GUI/CLI tool for testing REST APIs manually (sending requests, inspecting responses, chaining requests in a collection) – conceptually you already do this via curl or a browser fetch; Postman just gives it a UI and lets you save/organize test collections. 20%: create a collection, send GET/POST requests with headers/body, use an environment variable for a base URL.

GOOD to know / already strong (Class B)

Version control (Git/GitHub) – already daily-driver strength; no prep needed.

Code reviews, debugging – you already do this at Clink AI (Sentry-driven debugging, Git-tracked fixes) – ready to discuss directly.

LLM models & AI integration (good-to-have) – this is a genuine strength: you've shipped RAG pipelines, LLM tool calling, and AI agents (Echo, Vibe) – lead with this as a differentiator in interviews, since it's explicitly called out as "good to have."

Web scraping / data extraction, rule-based/ML-assisted analysis (good-to-have, e.g. fraud detection) – no direct experience; if asked, be honest and pivot to your DSA/analytical strength (CodeChef, 1000+ problems) as the transferable skill.

Priority if time is short

1. Flask basics (most likely to come up given "Python (Flask/Django)" is the headline backend ask).
2. Postman – quick, high-value, likely to be asked about directly ("testing via tools like Postman" is explicit in the JD).
3. MySQL syntax quirks vs. Postgres (small delta, don't over-invest).
4. Django only if the interview specifically leans that direction.
