

Tradelab Technologies Flutter Developer - What to Learn

MUST Learn (Class A keywords with no direct project experience)

- **Flutter & Dart** – this JD’s headline, non-negotiable requirement (“1+ years Flutter/Dart expertise”), and your mobile production experience is React Native, not Flutter. Bridge from React Native: both are cross-platform frameworks with a widget/component tree and hot reload – React components $\approx$ Flutter widgets. Build one small Flutter app with real-time data (a live-updating list via WebSocket) to have a concrete, relevant project before interviewing – generic to-do apps won’t demonstrate the low-latency, real-time focus this JD wants.
- **Flutter state management (Provider, Riverpod, BLoC)** – Flutter-specific state patterns. Bridge from Redux/MobX (which you know from Clink AI/Edfora): BLoC is architecturally closest to Redux (unidirectional data flow, event/state pairs via Streams); Provider/Riverpod are lighter-weight, closer to React Context or Zustand. Build your practice app with BLoC specifically, since it’s the most commonly expected pattern in production Flutter fintech apps.
- **Real-time data streaming for financial markets, applied** – you have real-time experience (Convex’s WebSocket-based sync in Echo, Vapi’s live call transcripts), but not specifically with market-data-style high-frequency streams. The concepts transfer (subscribe, reconcile, re-render on tick), but the volume/latency profile of live trading data is a different performance regime than typical app updates – worth understanding conceptually even without direct experience.

GOOD to Learn (strengthens the application, not blocking)

- **Security, encryption & compliance in fintech** – you have JWT/OAuth and secrets-management experience (Clerk, AWS Secrets Manager in Echo), but fintech-specific compliance context (data-at-rest encryption standards, regulatory requirements for trading platforms) is additional domain knowledge worth a skim.
- **Open-source Flutter contributions, high-frequency trading exposure, team leadership** – all listed as nice-to-haves; none are blocking. If you build the practice Flutter app above, consider open-sourcing it as a lightweight way to show initiative in this specific ask.

Fast-Ramp Note

This JD’s core requirement (1+ years Flutter/Dart) is a hard, specific bar your React Native background does not directly satisfy – this is a genuine framework switch, not an incremental stretch, and worth being upfront about if it comes up. Your real-time systems thinking (Echo’s WebSocket-based sync, Vapi’s live data) and state-management discipline (Redux/MobX) transfer conceptually, but a concrete Flutter + BLoC + WebSocket project is the single most valuable thing you can build before interviewing for this specific role.
